

Astro Blog Update Report

21 September 2026 | Features, implementation changes and verification

Publishing now starts with one Markdown file. The homepage and article pages read from the same validated content collection, replacing duplicated hardcoded post data.

What was added

Markdown publishing

Each article lives in `src/content/posts/`. Its filename determines its blog URL. The two existing posts were migrated with their original URLs and sample body text preserved.

Validated post metadata

Required title, description and date; optional tags and cover image. A cover requires a public image path and non-empty alternative text. Invalid metadata fails collection validation.

Automatic post listing and routes

The homepage loads posts from the collection, sorts newest first and shows an empty-state message when no posts exist. Article pages are generated from that same collection.

Article presentation

Pages now show publication dates, tag labels, optional cover images and an All posts link. Markdown styles cover headings, paragraphs, lists, links, quotations, images and code blocks.

Mobile and date consistency

Narrow screens receive smaller outer margins and content padding. Shared date formatting uses UTC, preventing the displayed calendar day from shifting with the server timezone.

Type safety and checks

Post arrays now explicitly use `CollectionEntry<"posts">[]` to provide types for sorting and mapping callbacks. Astro check and TypeScript 6 were added; every production build now runs type checking first.

Verification

Latest verification: **0 errors, 0 warnings and 0 hints** across 10 checked files. The production build generated five pages. Both article links, return navigation, and desktop/mobile layouts were checked in the browser.

Scope and current limits

The articles still contain placeholder text. Tags are display labels, with no tag archive pages yet. All post files are published, including future-dated posts; there is no draft mode. Search, RSS, sitemap, comments and a CMS were not added.

Files changed

Project: D:/Frontend/astro/astro-blog

This inventory covers the implementation work in this conversation. Paths below are relative to the project root.

File / status	Purpose
src/content.config.ts NEW	Defines the posts loader and metadata validation schema.
src/content/posts/getting-started.md NEW	Stores the first migrated article with its metadata and body.
src/content/posts/why-astro-fast.md NEW	Stores the second migrated article with its metadata and body.
src/components/PostDate.astro NEW	Reusable, typed date component with UTC formatting and a semantic time element.
src/pages/index.astro UPDATED	Reads and sorts the collection, renders dates, adds an empty state and explicitly types the post array.
src/pages/blog/[slug].astro UPDATED	Generates routes from posts, renders Markdown and metadata, adds article styles and explicitly types posts.
src/layouts/Layout.astro UPDATED	Applies global border-box sizing and improves mobile main-content spacing.
package.json UPDATED	Adds the check command, type checking before builds, @astrojs/check and TypeScript development dependencies.
pnpm-lock.yaml UPDATED	Records the added development tools and their resolved dependencies.
README.md UPDATED	Explains post creation, required fields, optional covers, URL naming, publishing and background dev commands.

Generated files

Astro refreshed generated types/content data under .astro/ and rebuilt the site under dist/. These are generated outputs, not files to edit when writing posts.

Adding your next post

1. Add a .md file directly inside src/content/posts/.
 2. Add title, description and date in frontmatter, then write the article.
 3. Run npm run build and deploy the updated dist/ output.
- Use npm run check whenever you only need type diagnostics.
